

## Banking Application Assignment: Backend Engineering Role

We would like you to create a banking application that supports the following operations via API

- Creation of account
- Deletion of account
- Money deposit
- Money withdrawal
- Money transfer
- International transfer
- Getting the balance
- List of accounts

The recommendation is to build it using Spring boot with internal caching of transactions. Use of the database is not required but great to see the design made in a way that it can support database integrations very easily in future.

The transactions should be at code & DB levels.

We expect you to write the production-quality code with Readme explaining its working and with sample requests.

*Please share the github repository link that contains the code, along with a docker file and command to run.*
